

Defining and Implementing Service Oriented Architectures (SOA) – From Theory to Practice

About this seminar

SOA has rapidly seized the momentum and center stage because it is seen as the key for enterprises to achieve business agility, improved quality of service, lowered total cost of ownership and to align business with technology. Over the past two years, many Fortune 1000 companies have started to embrace a SOA approach for initial development and integration projects. Many analysts predict that companies are now ready to take the next step – a more systematic adoption of service-oriented practices. However, just technologies like Web Services and the latest generation of development tools are not sufficient for successful implementation of an enterprise SOA.

SOA represents a unique and rare opportunity to bring IT and Business together. However, this opportunity implies an evolution and often an organizational change, especially in the role of IT within organization and in the way IT and Business work together. The current IT culture must evolve, looking beyond the scope of purely departmental goals to the requirements of the enterprise as a whole. IT must also change its support of the business – moving from the delivery of line of business applications to the encapsulation of business functions as services that can be used to compose ever-changing business processes. Finally, the traditional divide of application development and integration must give way to a more holistic approach – development with integration in mind (i.e. “development for integration”).

Service Oriented Architectures promise to improve every aspect of IT. Seamless B2B interactions, allowing companies to establish new business relationships and processes without the tedious grunt work that is usually involved when incompatible applications need to exchange information. The same should be true for integration behind the firewall, where legacy systems and packaged applications can now interoperate using standardized interfaces and protocols. And finally, new applications can be developed with less effort since much of their required functionality is already available to developers through an inventory of business services.

XML and Web Services provide a standards-based approach to implementing a Service Oriented Architecture, but it should not be overlooked that core business functionality still has to be implemented behind the interfaces of the business services. This requires a strong development methodology, as well as a comprehensive Middleware execution platform (i.e. J2EE Application Servers or .NET). The same applies to the integration of applications through a SOA approach. While service-based interfaces and standard access protocols provide for connectivity between applications, a complete B2B or EAI solution requires a Middleware Integration platform that provides a host of integration capabilities.

This seminar will give you insight into the key organizational challenges that IT managers face with the adoption of SOA and how to master them. It will discuss the important aspects of Enterprise Architecture that have to be addressed in order to make SOA projects successful. Furthermore, the seminar will provide you with an in-depth understanding of the concepts of Service Oriented Architectures, and how they can be mapped to Web Service technologies. You will gain insight how SOA can be applied to development and integration initiatives within your company. Today's predominant platforms for building new business applications – J2EE and .NET – will be examined in terms of their support for SOA, and the major integration approaches for B2B and EAI will be looked at from a SOA perspective.
